Interactive workflow example

Abstract

We study whether shared representations improve sample efficiency for two-arm manipulation. This PDF is sample content for the SuperSurfer workflow playground. Values and claims in the interactive research view are illustrative, not experimental evidence.

1 Method

We compare a pretrained visual encoder with a model trained from scratch. Both methods use the same data split, optimizer, and training budget. Training and validation loss are reported on the same step axis, with no test-set tuning.

2 Reporting

Overlay training and validation curves between methods. Label every axis, distinguish data splits, and report the identity of the checkpoint and dataset. A favorable validation curve motivates further evaluation; it does not establish success on an unseen task.

3 Reviewing with an agent

Select a paragraph in this PDF and click Add to chat. The selection becomes a small context attachment, ready for your question or instruction. This demo uses scripted responses and does not contact live agents.

4 Held-out evaluation

Compare both methods on held-out scenes. Keep the protocol fixed, then report uncertainty across three independent seeds. Inspect representative failures before expanding the study.

5 A persistent workspace

A task can combine writing, coding, and research. The files remain accessible in the sidebar while editors, PDF viewers, results, and notes are arranged on its pages. Resize panels, enter fullscreen, and drag a panel into the sidebar in Arrange mode.

6 What this preview demonstrates

The PDF viewer renders all pages and supports selectable text. Uploaded PDFs remain in the current browser session. Source files and layout changes are stored locally in the browser. Remote compute, real agent execution, and a live LaTeX compiler belong to the connected SuperSurfer application.
